Abstract. Labuhan Sangoro, located in Saleh Bay, Sumbawa Regency, West Nusa Tenggara, Indonesia, is one of the areas developed for cultivation of seaweed species *Kappaphycus alvarezii*. In 2023, the cultivation activities experienced crop failure due to an outbreak of ice-ice disease. This incident has caused significant labor and financial losses for the farmers. It is suspected that biological factors (bacteria) play a role in the emergence of this disease. Therefore, this study aimed (1) to identify the bacteria living in the waters (ice-ice-infected seaweed cultivation site) and (2) to find potential bacterial species responsible for causing the ice-ice disease. The target of this research was to molecularly identify the potential bacterial species known to infect *K. alvarezii*, causing the disease. The method used in this research was exploratory descriptive. Samples were collected from 4 points (*K. alvarezii* cultivation locations infected by ice-ice). Each point was represented by 2 depths (surface and bottom waters). Sampels analysis employed a culture-independent approach using metabarcoding (eDNA) analysis. This approach can be used to examine the genomes available in the environmental samples, thus allowing the identification of a wider range of bacterial species. As such, this approach offers greater opportunities to discover potential bacterial species that cause the ice-ice disease. In this research, the bacterial composition at two depths (surface and bottom waters) has been comprehensively understood. The major phyla responsible for important roles in organic matter decomposition, nutrient recycling, supporting primary production, and maintaining ecosystem balance are Cyanobacteria and Proteobacteria. The ice-ice disease in *K. alvarezii* culture is associated with certain bacterial species such as *Vibrio* spp. and *Pseudoalteromonas* sp. also found in the sampling locations.

Key Words: environmental DNA, ice-ice disease, *K. alvarezii*, marine bacteria, Saleh Bay.

Introduction. *Kappaphycus alvarezii* has become one of the Indonesian leading products, with national production reaching 8.3 million tons in 2013, the first rank in global production (Asaf et al 2021). In West Nusa Tenggara (NTB), the development of *K. alvarezii* cultivation is focused on several areas, one of which is Saleh Bay area in Sumbawa Regency. The selection of this area is based on its potential to provide environmental services along with the ecological resources it possesses (Yulius et al 2017). The growth of *Kappaphycus alvarezii*, a type of red algae known for its carrageenan content (Rupert et al 2022), has a notable obstacle in the form of ice-ice disease. Initially documented in the Philippines in 1974, this ailment has

subsequently emerged as a significant impediment in the cultivation of seaweed, resulting in extensive reductions in production and adversely impacting the economic well-being of coastal communities (Santoso & Nugraha 2008; Arasamuthu & Edward 2018; Aris et al 2020). Ice-ice is a disease caused by opportunistic pathogens that usually attack when environmental conditions are not optimal for seaweed survival (Riyaz et al 2019). The disease is distinguished by the presence of white and tender sections on the affected seaweed, indicating a significant disturbance in its typical structure and function (Arisandi & Farid 2014; Aris & Labenua 2020). In NTB, ice-ice outbreak was experienced by *K. alvarezii* cultivations in the waters of Labuhan Sangoro, Saleh Bay, Sumbawa Regency. This occurred in early 2023 and resulted in significant labor and financial losses for the farmers, most of whom rely on this activity for their livelihood (Astriana et al 2023).

Both abiotic and biotic variables influence the occurrence of ice-ice infection (Tahiluddin & Terzi 2021; Azis et al 2022). Unfavorable climatic circumstances such as excessive temperature, irradiance, and salinity can promote the disease (Erbabley & Kelabora 2018; Tahiluddin & Terzi 2021). Additionally, opportunistic bacterial pathogens play a vital part in the infection process (Azis et al 2022). Understanding the bacterial composition of affected areas on ice-ice disease is critical for creating efficient disease management techniques.

Traditional methods of identifying bacterial pathogens frequently rely on cultivation procedures, which can be time-consuming and may fail to capture the full diversity of the microbial population (Afanti & Darmayati 2019). Molecular approach that is currently widely used is environmental DNA (eDNA) metabarcoding. Environmental DNA refers to the DNA of an organism and extra-organismal DNA originating from marine, terrestrial, and aerial environments, such as water and sediment samples (Pranata et al 2022). DNA metabarcoding, a high-throughput sequencing approach, is an effective tool for evaluating numerous DNA sequences from complex microbial communities at the same time (Abdelfattah et al 2018). This method enables the identification and quantification of diverse bacterial species found in seaweed samples, offering a thorough understanding of the microbial dynamics involved in ice-ice disease.

Recent research has isolated a wide variety of seaweed-associated bacteria from *K. alvarezii*, including species from the genera *Alteromonas*, *Aestuariibacter*, *Idiomarina*, *Jejuia*, *Halomonas*, *Primorskyibacter*, *Pseudoalteromonas*, *Ruegeria*, *Terasakiella*, and *Vibrio* (Azizi et al 2018). These bacteria can cling to the seaweed surface and induce infection, resulting in a considerable drop in seaweed production and quality. Certain bacterial strains, such as *Vibrio alginolyticus* strain ABI-TU15, have been related to agarolytic activity and pathogenic potential (Azizi et al 2018).

The molecular characterisation of bacteria causing ice-ice disease found that the isolated bacteria are closely related to the genera *Vibrio*, *Pasteurella*, *Edwardsiella*, *Plesiomonas*, *Chromobacterium* (Azis et al 2022), *Alteromonas*, *Pseudoalteromonas*, and *Aurantimonas* (Kane et al 2016). These findings emphasize the necessity of understanding the genetic variety of the causal organisms in ice-ice illness in order to create tailored treatments. The purpose of this study is to use DNA metabarcoding to determine the bacterium composition at ice-ice infected *K. alvarezii* seaweed aquaculture sites. Using this advanced technique to analyze bacterial communities, we can get insight into the complex interactions between seaweed and its microbial environment. This understanding will help build more effective disease management techniques, as well as improve the general health and production of *K. alvarezii* farms.

Material and Method

Sampling. The study was carried out in the Labuhan Sangoro Sea waters, namely in the Saleh Bay area of Sumbawa Regency, from May to October 2024. The sampling was conducted using a purposive approach, specifically targeting places where seaweed agricultural activities take place. Four samples were collected from specific places where *K. alvarezii* seaweed cultivation

was affected by ice-ice. Samples of seawater from two specific depths were collected: the surface (where the seaweed is grown at a depth of around 30-50 cm), and the near-bottom region of the water.

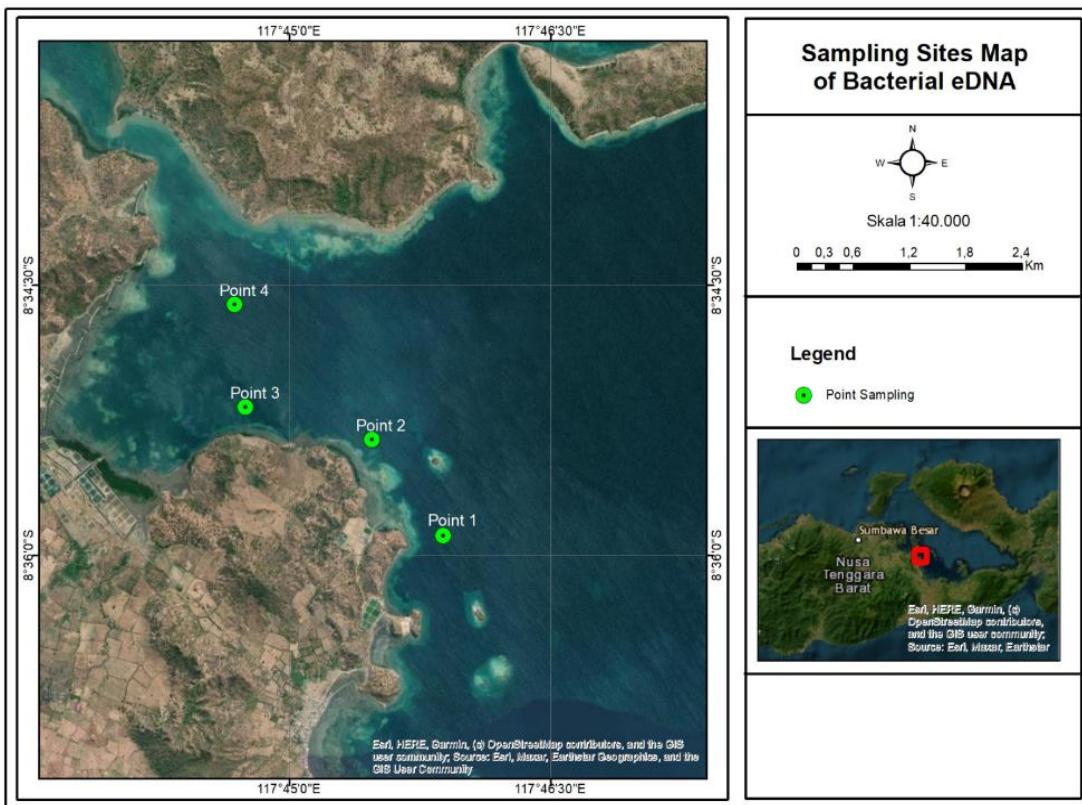

Figure 1. Sampling points at Labuhan Sangoro, Saleh Bay, Sumbawa Regency, West Nusa Tenggara.

Genomic material isolation. The DNA extraction from the samples was performed using the Qiagen Blood and Tissue DNA Extraction Kit, following the instructions provided by the manufacturer. The initial polymerase chain reaction (PCR) was performed to amplify the specific area of the 16S gene using 341F-518R primers, as described by Zhou et al (2017). The initial PCR reaction consisted of 10 µL of Phanta Flash Master Mix (2x), 1 µL of each 10 nM primer (F and R), 11 µL of ddH₂O, and 2 µL of DNA template. The DNA amplification PCR profile consisted of the following phases. The process involves several steps: (1) heating the template DNA at 95°C for 5 min to prepare it for denaturation; (2) denaturing the template DNA at 98°C for 30 seconds; (3) annealing at 67°C for 30 seconds; (4) extending the DNA at 72°C for 30 seconds; and (5) performing a final extension at 72°C for 5 min. These steps are repeated for 35 cycles, starting from step (2) and ending with step (4). The 96 Universal pEqStAR PCR machine was utilized to detect any presence of contamination, employing negative controls in the form of a blank template. The PCR product quality was assessed by seeing it through electrophoresis on a 2% agarose gel, prepared with 100 mL of TAE buffer and 1 g of agarose. A 2 µL portion of the PCR result was subsequently placed into each agarose well along with a 100 bp DNA ladder in one of the wells. The electrophoresis machine was run at 100 volts for 30 min, and the results were seen using UV fluorescence via an Alpha Imager Mini Gel Documentation System.

For indexing purposes, all triplicate PCR results that passed the electrophoresis quality control underwent a second PCR. The IDT double index and Illumina sequencing adaptor for

Illumina Nextera DNA Unique Dual Index, Set B were added to the target amplicon in the second PCR. The PCR cycle comprised an initial denaturation at 95°C (3 min), then 9 cycles of 95°C for 30 seconds, 55°C for 30 seconds, 72°C for 30 seconds, and a final extension at 72°C for 5 min. PCR purification was undertaken on the first PCR and second PCR products using AMPure XP before proceeding to the next stage. The amplicon library was quantified using a Qubit fluorometer, then normalized at equal concentration. DNA sequencing was performed on a NovaSEQ6000.

Taxonomic classification. The datasets were demultiplexed into FASTQ files and then imported into Quantitative Insights into Microbial Ecology (QIIME2; v2024.5). The raw sequence reads were quality-checked using the “qiime demux summarize” function and denoised using DADA2 (q2-dada2 denoise-paired) (Callahan et al 2016). The “q2-feature-table tabulate-seqs” command was used to generate representative sequences (rep-seqs). Taxonomic identifications (ids) represented the respective sequences assigned to ASVs against the Silva-138-99-nb-classifier (Yilmaz et al 2014).

Results. The taxonomic analysis revealed a diverse range of bacterial phyla across both sites. The most abundant phylum at both locations was Cyanobacteria, with class Oxyphotobacteria, followed by Proteobacteria, with class Alphaproteobacteria (Figures 2 and 3).

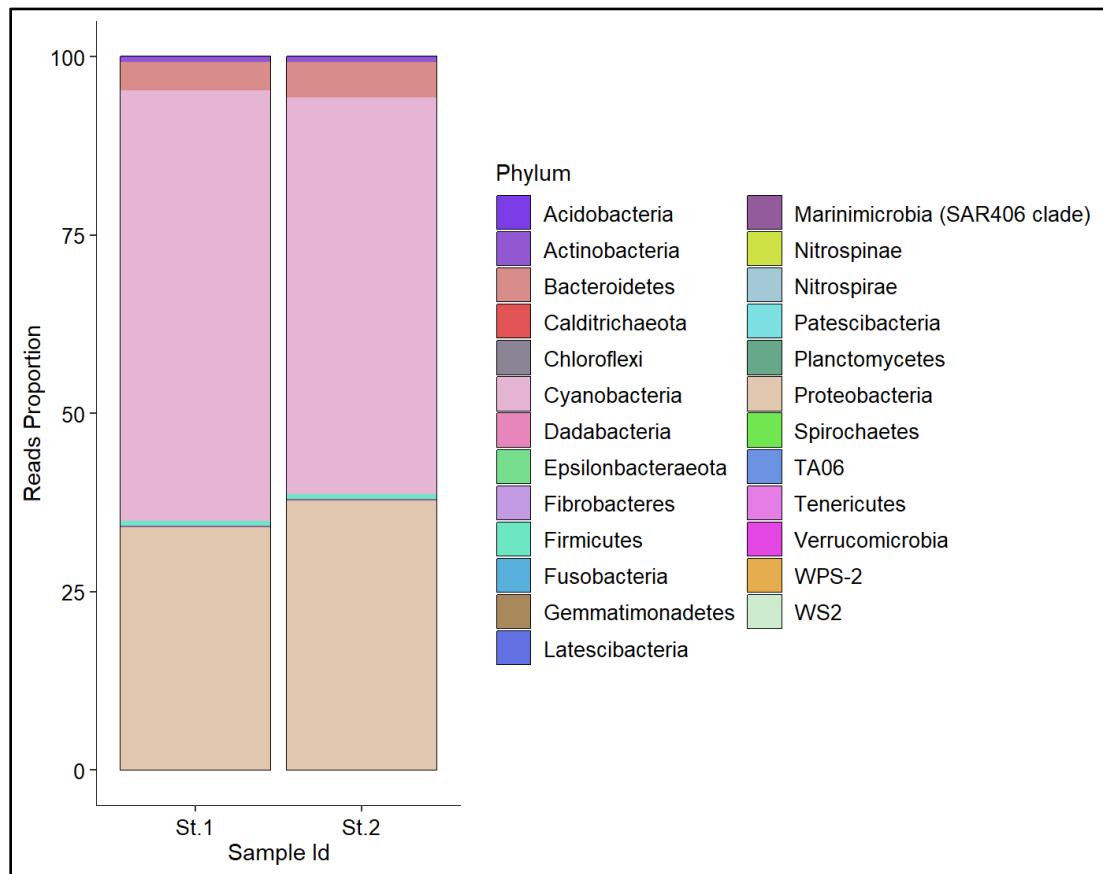

Figure 2. Taxa identified at the phylum level across all samples based on read proportion.

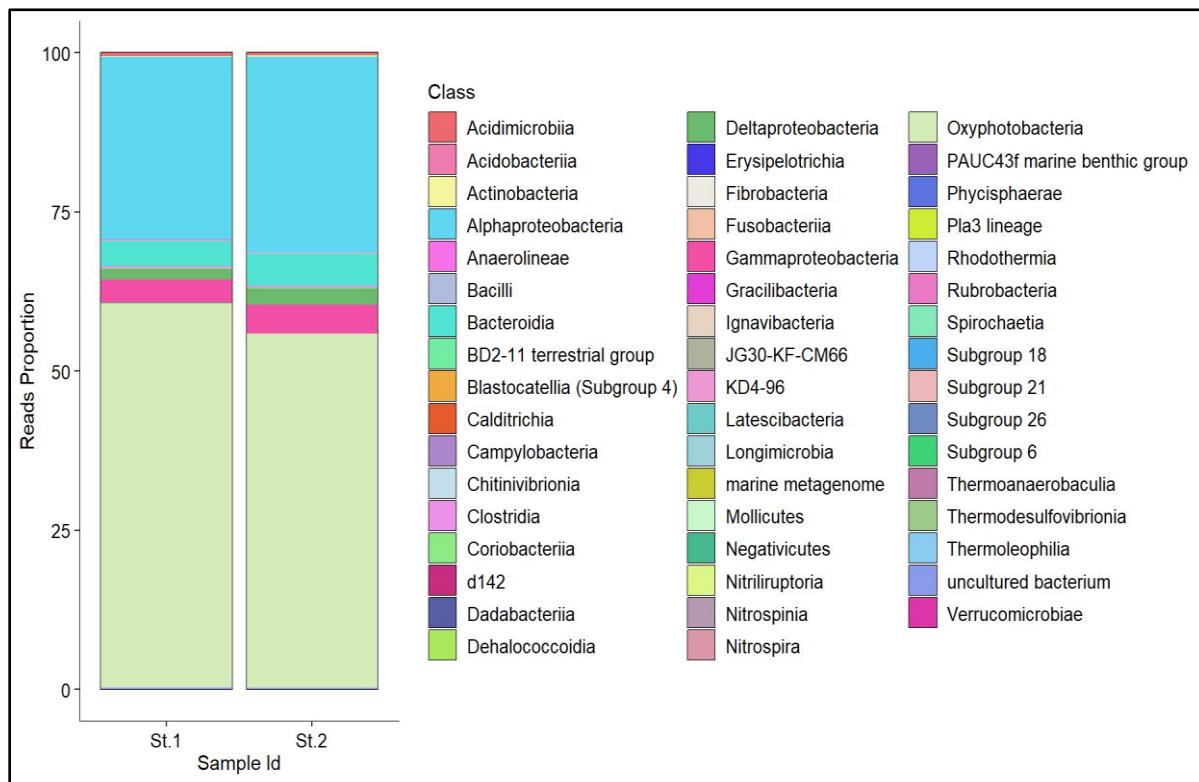

Figure 3. Taxa identified at the class level across all samples based on read proportion.

The Krona chart (Figure 4) at site 1, located near the seabed in the cultivation region of *K. alvarezii* infected with ice-ice, shows that 60% of the total bacteria detected were Oxyphotobacteria (phylum Cyanobacteria). Among these, 54% were *Synechococcus* CC9902, 2% were *Cyanobium* PCC-6307, and 4% were other types. Subsequently, the phylum Proteobacteria comprises 34% of the total, with 28% being Alphaproteobacteria, 4% Gammaproteobacteria, and 2% Deltaproteobacteria. Within the class Gammaproteobacteria, 0.1% were comprised by *Vibrio* (339 bacteria), which included *Vibrio azureus*, *Vibrio* sp. S573, and *Vibrio aerogenes*. Furthermore, the phylum Bacteroidetes accounts for up to 4%.

At site 2, located at a depth of around 30-50 cm (which corresponds to the depth of *K. alvarezii* cultivation), the investigation revealed 56% Cyanobacteria, 38% Proteobacteria, and 5% Bacteroidetes. The discovered phylum Cyanobacteria consists of the class Oxyphotobacteria, which includes the genus *Synechococcus* CC9902 (43%) and other genera. Within the phylum Proteobacteria, Alphaproteobacteria accounts for 31%, Gammaproteobacteria for 5%, and Deltaproteobacteria for 3% of the phylum. Within the Gammaproteobacteria class, a total of 0.3% were identified as *Vibrio* (495 bacteria), including *Vibrio azureus*, *Vibrio* sp. S573, *Vibrio aerogenes*, and uncultured *Vibrio* sp. Apart from *Vibrio* at site 2, uncultured *Pseudoalteromonas* sp. was also present in tiny amounts.

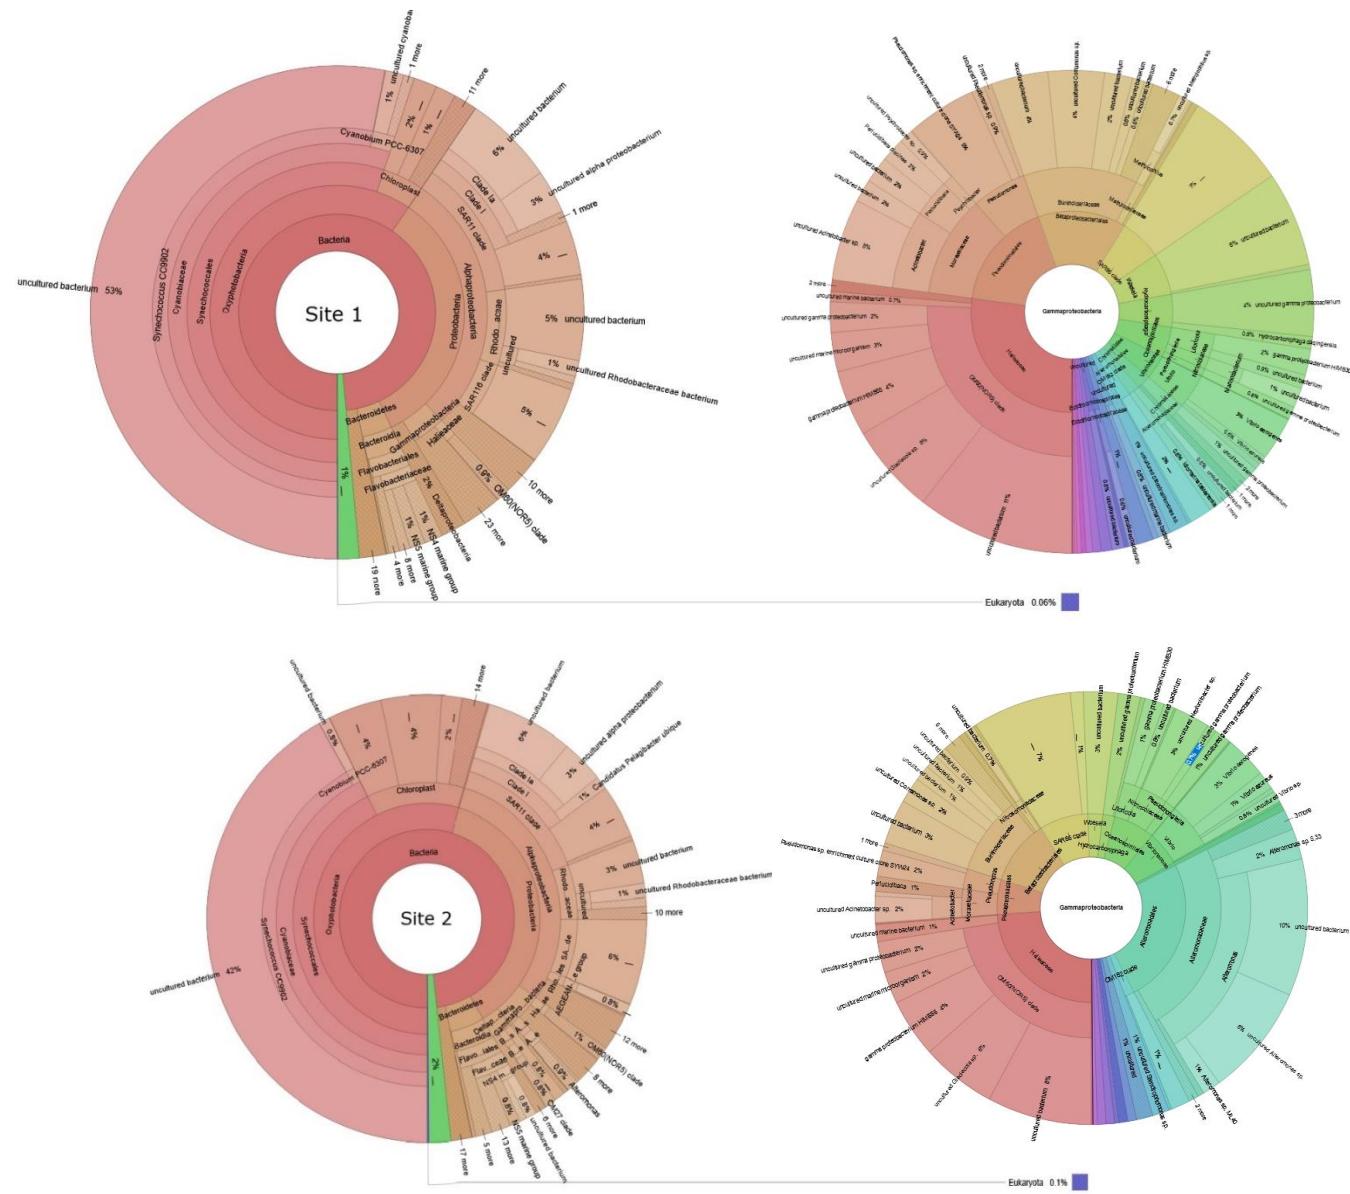

Figure 4. Krona plots visualizing taxonomic hierarchies based on read proportions for each sample.

Discussion. Understanding the health and output of these ecosystems depends on knowledge of bacterial populations in seaweed farming. Popular seaweed species *K. alvarezii* is frequently afflicted by ice-ice disease, which can seriously limit its productivity and development.

Cyanobacteria, including *Acrophormium* at Site 1 and *Cyanobium* at Site 2, were identified. These bacteria are notable for their photosynthetic abilities, which contribute to primary production in the ecosystem.

The presence of *Synechococcus* CC9902 in the cultivation region of *K. alvarezii* does not directly indicate a negative impact on the health of *K. alvarezii*. *Synechococcus* CC9902 is a dominant species in the phylum Cyanobacteria, which accounts for 54% of the total bacteria detected at Site 1 and 43% at Site 2. This dominance suggests that *Synechococcus* CC9902 is well-adapted to the environment and likely plays a significant role in the ecosystem, possibly contributing to nutrient cycling and photosynthetic activity (Kim et al 2018). While *Synechococcus* CC9902 itself does not appear to be directly harmful to *K. alvarezii*, the overall bacterial community and environmental conditions can influence the health of the seaweed. For example, changes in salinity, temperature, and light intensity can affect *K. alvarezii* growth and susceptibility to diseases like ice-ice disease (Arasamuthu & Edward 2018).

The ice-ice disease in *K. alvarezii* is known to be influenced by a combination of environmental stressors and opportunistic bacterial pathogens, such as *Vibrio* species. The presence of these pathogens, rather than *Synechococcus* CC9902, is more directly linked to the disease. The presence of *Vibrio* species, which are known to be associated with ice-ice disease in *K. alvarezii*, is noted in both sites. This suggests that these bacteria could play a role in the disease's etiology, although the exact mechanism and impact on the disease progression are not detailed in the provided information (Azizi et al 2018; Riyaz et al 2019).

Vibrio bacteria play a significant role in the development of ice-ice disease in *K. alvarezii* cultures. Some studies have identified *V. alginolyticus* as one of the primary bacteria causing ice-ice disease in *K. alvarezii*. Other *Vibrio* species, such as *Vibrio* sp. (P11), have also been implicated in the disease (Largo et al 1995; Tahiluddin & Terzi 2021).

The differences in bacterial composition between Site 1 (seabed) and Site 2 (depth 30-50 cm) provide insights into the ecological dynamics of *K. alvarezii* culture. For instance, Site 1 may suffer higher levels of organic matter breakdown due to the presence of additional Bacteroidetes species, such as *Actibacter* and *Aureicoccus*. Site 2 might feature a more diversified community with a higher presence of Actinobacteria such *Candidatus actinomarina* and *Gordonia*, indicating a larger range of metabolic activities.

Conclusions. By means of DNA metabarcoding, the bacterial composition at two separate sites within *K. alvarezii* culture locations has been thoroughly understood. Important responsibilities in decomposing organic matter, recycling nutrients, supporting primary production, and preserving ecosystem balance are played by the leading phyla—Cyanobacteria, and Proteobacteria. Ice-ice disease in *K. alvarezii* cultures is associated with particular bacterial species like *Vibrio* spp. and *Pseudoalteromonas* sp. Understanding the microbial dynamics involved will help properly manage and conserve *K. alvarezii* aquaculture systems.

Acknowledgements. The authors would like to thank University of Mataram for funding this research through the 2023 Research and Community Service Grant program. The authors also deeply appreciate the people of Labuhan Sangoro Village for helping the team in sampling activities and The Agency of Environmental Service of Sumbawa Regency, NTB for giving us much information regarding ice-ice disease outbreak.

Conflict of Interest. The authors declare that there is no conflict of interest.
